Neural Networks

Overall Structure

- Mathematical model based off human brain.
- Objective is to approximate a function f^* using mapping with parameters Θ : $\mathbf{f}_{\Theta}(\mathbf{x})$.
- Universal Approximation Theorem states a neural network can approximate (almost) any function if it is complex enough.
- Each node output is a weighted sum of previous node outputs, passed through an activation function.

Neural Networks

Training

- Weights trained such that (ideally convex) loss function is minimized e.g. Mean Squared Error: $\min_{\Theta} \frac{1}{2} || \mathbf{y} \mathbf{f}_{\Theta}(\mathbf{x}) ||_2^2$.
- Back-propagation finds partial derivatives of loss function with respect to weights.
- Gradient descent uses these partial derivatives to optimize network.

(Amortized) Variational Inference

Bayesian Inference

• Fundamental problem in Bayesian computation is to estimate posterior densities p(z|x):

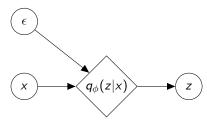

$$p(z|x) \propto \underbrace{p(z)}_{\text{Prior Likelihood}} \underbrace{p(x|z)}_{\text{Likelihood}}$$
.

- Typical MCMC methods are slow with large datasets or high dimensional data.
- Variational Inference is a solution.

(Amortized) Variational Inference

Introduction

- Amortized variational inference approximates p(z|x) with a different distribution $q_{\phi}(z|x)$.
- $q_{\phi}(z|x)$ is a neural network with parameters ϕ that takes in data x and random noise $\epsilon \sim \pi(\epsilon)$ and outputs samples $z \sim q_{\phi}(z|x)$.
- Typically $\pi(\epsilon) = \mathcal{N}(0, I_{n \times n})$.

(Amortized) Variational Inference Network Training

• Minimize the **n**egative of the **e**vidence **lower bo**und NELBO(q):

$$\min_{\phi} \mathit{NELBO}(q) = -\mathbb{E}_{q_{\phi}(z|x)q^*(x)}[\log p(x|z)] + \mathbb{E}_{q^*(x)}[\mathit{KL}(q_{\phi}(z|x)||p(z))].$$

 This is the same as minimizing the reverse KL divergence between the two distributions:

$$\mathbb{E}_{q^*(x)}[\mathit{KL}(q(z|x)||p(z|x))] = \mathbb{E}_{q^*(x)q(z|x)}\left[\log\left(\frac{q(z|x)}{p(z|x)}\right)\right]$$

• Taking expectation with respect to dataset distribution $q^*(x)$ allows model to work for different data points.

(Amortized) Variational Inference

Problems with Implicit Distributions

$$\min_{\phi} \underbrace{-\mathbb{E}_{q_{\phi}(z|x)q^*(x)}[\log p(x|z)]}_{\text{Likelihood}} + \underbrace{\mathbb{E}_{q^*(x)}[\mathit{KL}(q_{\phi}(z|x)||p(z))]}_{\text{Log Density Ratio}}.$$

- $q_{\phi}(z|x)$ is a neural network so extremely difficult to evaluate density function but easy to draw samples, we therefore say that it is **implicit**.
- Use density ratio estimation to evaluate $\frac{q_\phi(z|x)}{p(z)}$ in $KL(q_\phi(z|x)||p(z))$.
- The prior p(z) can also be implicit.
- We call this the "prior-contrastive" formulation.
- "Joint-contrastive" formulation used with implicit likelihood minimizes $NELBO(q) = \underbrace{KL(q(z,x) || p(z,x))}_{}$.

Log Density Ratio

Class Probability Estimation

We want to estimate $\frac{q(u)}{p(u)}$.

- **①** Define discriminator function that finds probability that a sample u came from q(u): $D_{\alpha}(u) \simeq P(u \sim q(u))$, so that $\frac{q(u)}{p(u)} \simeq \frac{D_{\alpha}(u)}{1 D_{\alpha}(u)}$.
- ② $D_{\alpha}(u)$ is neural network parametrised by α , sigmoid activation function used for output layer
- **③** Train discriminator with Bernoulli loss: $\min_{\alpha} -\mathbb{E}_{q(u)}[\log D_{\alpha}(u)] \mathbb{E}_{p(u)}[\log (1 D_{\alpha}(u))].$
- **3** Optimal discriminator is $D_{\alpha}^{*}(u) = \frac{q(u)}{q(u)+p(u)}$.

Class Probability Estimation

Prior-Contrastive Application:

$$\min_{\alpha} - \mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log D_{\alpha}(z,x)] - \mathbb{E}_{q^*(x)p_{\theta}(z)}[\log(1-D_{\alpha}(z,x))]$$

$$\min_{\phi} \underbrace{-\mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log p(x|z)]}_{\text{Likelihood}} + \underbrace{\mathbb{E}_{q^*(x)q_{\phi}(z|x)}\left[\log \frac{D_{\alpha}(z,x)}{1-D_{\alpha}(z,x)}\right]}_{\text{Log Density Ratio}}$$

Joint-Contrastive Application:

$$egin{aligned} \min_{lpha} - \mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log D_{lpha}(z,x)] - \mathbb{E}_{p(z)p(x|z)}[\log(1-D_{lpha}(z,x))] \ & \min_{\phi} \mathbb{E}_{q^*(x)q_{\phi}(z|x)}\lograc{D_{lpha}(z,x)}{1-D_{lpha}(z,x)} \end{aligned}$$

Program alternates between several optimisation steps of discriminator and one optimisation step of posterior.

Divergence Minimisation

Theorem

If f is a convex function with derivative f' and convex conjugate f^* , and \mathcal{R} is a class of functions with codomains equal to the domain of f', then we have the lower bound for the f-divergence between distributions p(u) and q(u):

$$D_f[p(u)||q(u)] \ge \sup_{r \in \mathcal{R}} \{ \mathbb{E}_{q(u)}[f'(r(u))] - \mathbb{E}_{p(u)}[f^*(f'(r(u)))] \},$$

with equality when r(u) = q(u)/p(u).

For the reverse KL divergence, $f(u) = u \log u$ so we have

$$\mathit{KL}[q(u)||p(u)] \geq \sup_{r \in \mathscr{R}} \{\mathbb{E}_{q(u)}[1 + \log r(u)] - \mathbb{E}_{p(u)}[r(u)]\}$$

Divergence Minimisation

- Let our ratio estimator be a neural network parametrised by α : $r_{\alpha}(u) \simeq \frac{q(u)}{p(u)}$.
- Maximise the lower bound w.r.t. α until equality, which is when $r_{\alpha}(u) = \frac{q(u)}{p(u)}$. The optimisation problem for this is

$$\min_{\alpha} - \mathbb{E}_{q(u)}[\log r_{\alpha}(u)] + \mathbb{E}_{p(u)}[r_{\alpha}(u)].$$

• Obviously our optimal ratio estimator is $r_{\alpha}^{*}(u) = \frac{q(u)}{p(u)}$.

Divergence Minimisation

Prior-Contrastive Application:

$$\begin{split} & \min_{\alpha} - \mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log r_{\alpha}(z,x)] + \mathbb{E}_{q^*(x)p(z)}[r_{\alpha}(z,x)] \\ & \min_{\phi} \underbrace{-\mathbb{E}_{q^*(x)q_{\phi}(z|x)}\left[\log p(x|z)\right]}_{\text{Likelihood}} + \underbrace{E_{q^*(x)q_{\phi}(z|x)}[\log r_{\alpha}(z,x)]}_{\text{Log Density Ratio}} \end{split}$$

Joint-Contrastive Application:

$$\min_{\alpha} -\mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log r_{\alpha}(z,x)] + \mathbb{E}_{p(z)p(x|z)}[r_{\alpha}(z,x)]$$

$$\min_{\phi} \mathbb{E}_{q^*(x)q_{\phi}(z|x)}[\log r_{\alpha}(z,x)]$$

Algorithm Generalisation

- Actually, $f(u) = u \log u (u+1) \log(u+1)$ and $D(u) = \frac{r(u)}{r(u)+1}$ leads to class probability estimation equations.
- The upper bound f-divergence is $2JS(p(u)||q(u)) \log 4$, we call this the GAN divergence.
- To formulate optimisation problems for density ratio estimation, choose either reverse KL or GAN f-divergence upper bound and estimator parametrisation:
 - Class Probability Estimator $D_{lpha}(u) \simeq rac{q(u)}{q(u) + p(u)}$
 - Direct Ratio Estimator $r_{\alpha}(u) \simeq \frac{q(u)}{p(u)}$
 - Direct Log Ratio Estimator $T_{\alpha}(u) \simeq \log \frac{q(u)}{p(u)}$.

Optimal Estimator Experiment

Experiment Outline

$$\begin{aligned} p(z_1,z_2) &\sim \mathcal{N}(0,\sigma^2 I_{2\times 2}) \\ p(x|\boldsymbol{z}) &\sim \textit{Exp}(3+\max(0,z_1)^3+\max(0,z_2)^3) \end{aligned}$$

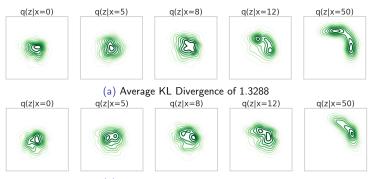

- Posterior is flexible and bimodal.
- Use Gaussian KDE to find 'true' KL divergence for $q_{\phi}(z|x=0,5,8,12,50)$.

Optimal Estimator Experiment

Experiment Outline

- Aim of this experiment is to verify that choice of estimator does not matter as long as it reaches optimality.
- Low training rate with high estimator to posterior optimisation ratio (100:1).
- High posterior iterations.

Optimal Estimator Experiment

Results

Algorithm	Mean KL Divergence	Standard Deviation
JC Reverse KL - $D_{\alpha}(z,x)$	1.3416	0.0068
JC Reverse KL - $r_{\alpha}(z,x)$	1.3397	0.0066
JC Reverse KL - $T_{\alpha}(z,x)$	1.3446	0.0108
$JC \; GAN - D_{\alpha}(z,x)$	1.3648	0.0242
JC GAN - $r_{\alpha}(z,x)$	1.3657	0.0302
JC GAN - $T_{\alpha}(z,x)$	1.3670	0.0387

- Prior-contrastive posteriors fully converged at ≈ 1.325 .
- No significant difference in convergence between estimators in each *f*-divergence.
- Reverse KL converged faster in joint-contrastive context.

Undertrained Estimator Experiment

Experiment Outline

- Estimators are similar when they are optimal but what if they are not optimal?
- Same inference experiment again.
- Significantly reduce amount of estimator training between posterior iterations.
- Increased posterior training rate.

Undertrained Estimator Experiment

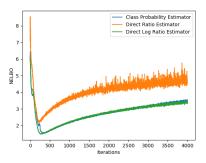

Results

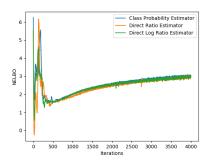

Algorithm	Mean KL Divergence	Standard Deviation
JC Reverse KL - $D_{\alpha}(z,x)$	1.3786	0.0286
JC Reverse KL - $r_{\alpha}(z,x)$	1.3934	0.0410
JC Reverse KL - $T_{\alpha}(z,x)$	1.4133	0.0597
JC GAN - $D_{\alpha}(z,x)$	1.4017	0.0286
JC GAN - $r_{\alpha}(z,x)$	1.4086	0.0555
JC GAN - $T_{\alpha}(z,x)$	1.4214	0.0518

- Reverse KL divergence significantly better than GAN divergence.
- $D_{\alpha}(z,x) < r_{\alpha}(z,x) < T_{\alpha}(z,x)$

Undertrained Estimator Experiment

Joint-Contrastive NELBO Plots

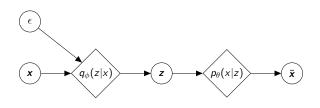

(a) GAN Divergence

- (b) Reverse KL Divergence
- Unclear why direct ratio estimator has unusual NELBO plot: posterior convergence was not affected.
- Reverse KL Divergence has initial instability.

Autoencoder Experiment

Autoencoders

- Likelihood $p_{\theta}(x|z)$ is now a neural network.
- Posterior $q_{\phi}(z|x)$ represents data x as lower dimensional latent z.
- Likelihood $p_{\theta}(x|z)$ reconstructs data \tilde{x} from z.
- Generate new data \tilde{x} using z from p(z).

$$\min_{ heta,\phi} - \mathbb{E}_{q_\phi(z|x)q^*(x)}[\log p_ heta(x|z)] + \mathbb{E}_{q^*(x)}[\mathit{KL}(q_\phi(z|x)||p(z))]$$

Autoencoder Experiment

Experiment Outline

- ullet MNIST dataset 28 imes 28 grey-scale images of handwritten digits
- Joint-contrastive context not tested here.
- Again use undertrained estimator.
- Use reconstruction error $||x \tilde{x}||^2$ as metric.
- Perform experiment with low dimensional latent space (2 dimensions) and high dimensional latent space (20 dimensions).
- Low dimensional case had similar results to previous experiment.

Generation Experiment

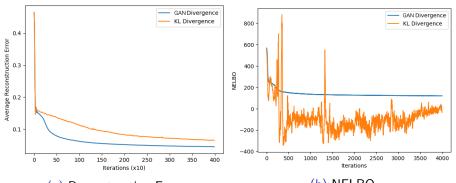

Results - high dimensional latent space

Algorithm	Mean Reconstruction Error	Standard Deviation
PC GAN - $D_{\alpha}(z,x)$	0.0444	0.0017
PC Reverse KL - $D_{\alpha}(z,x)$	0.0647	0.0019

- Direct ratio and direct log ratio estimators attempted to store numbers exceeding float64(max).
- Exponential of $T_{\alpha}(z,x)$ taken in loss function.
- $D_{\alpha}(z,x)$ ranges in (0,1).
- Value before sigmoid activation function for $D_{\alpha}(z,x)$ is log density ratio.
- This time GAN divergence leads to better convergence than reverse KL.

Autoencoder Experiment

Results - high dimensional latent space

(a) Reconstruction Error

- (b) NELBO
- As before, GAN divergence is more stable.
- Recall reverse KL divergence is initially unstable but stabilizes later.
- In this case it fails to stabilise by the end of the program runtime.

Theory Choice of *f*-divergence

- Nowozin's f-GAN paper shows empirically that the reverse KL divergence is superior when it is additionally used to optimize the posterior.
- Intuitive that the *f*-divergence used to optimize posterior is the best upper bound for estimator.

Further Estimator Loss Function Analysis

Estimator Parametrisation

- $D_{\alpha}(u)$ has smallest bound of (0,1), followed by $r_{\alpha}(u) \in \mathbb{R}^+$ and $T_{\alpha}(u) \in \mathbb{R}$.
- The density ratio changes every time the posterior is optimised, and the estimator must catch up.
- $D_{\alpha}(u)$ has a strictly lower displacement than $r_{\alpha}(u)$, that is, $|D_{\alpha}^{(n+1)}(u) D_{\alpha}^{(n)}(u)| < |r_{\alpha}^{(n+1)}(u) r_{\alpha}^{(n)}(u)|$.

Summary

- The class probability estimator $D_{\alpha}(u) \simeq \frac{q(u)}{q(u)+p(u)}$ is the 'best' parametrisation as it can store the highest density ratios.
- Reverse KL divergence upper bound demonstrates initial instability (especially when estimator is undertrained) but leads to faster convergence when it stabilizes.
- Outlook
 - Still unclear exactly why reverse KL divergence is more unstable but more accurate when stable.
 - Several more *f*-divergences exist which have unknown stability when undertrained.
